

# Involvement of Transcription Factor Encoded by the Mouse *mi* Locus (MITF) in Expression of p75 Receptor of Nerve Growth Factor in Cultured Mast Cells of Mice

By Tomoko Jippo, Eiichi Morii, Kumiko Tsujino, Tohru Tsujimura, Young-Mi Lee, Dae-Ki Kim, Hiroshi Matsuda, Hyung-Min Kim, and Yukihiko Kitamura

The *mi* locus of mice encodes a member of the basic-helix-loop-helix-leucine zipper (bHLH-Zip) protein family of transcription factors (hereafter called MITF). Cultured mast cells (CMCs) of *mi/mi* genotype showed a poor response to nerve growth factor (NGF). Addition of NGF to the suboptimal dose of interleukin-3 (IL-3) increased the plating efficiency of normal (+/+) CMCs but not *mi/mi* CMCs. Although +/+ CMCs were berberine sulfate–negative when cultured with IL-3, +/+ CMCs became berberine sulfate–positive when cultured in the presence of both IL-3 and NGF, which suggested increased heparin content. In contrast, NGF did not influence the phenotype of *mi/mi* CMCs. The poor response of *mi/mi* CMCs to NGF was attributed to the deficient expression of p75 NGF receptor. The purpose of the present study is to examine the effect of MITF on p75 gene transcription. Overexpression of +-MITF or *mi*-MITF was observed in *mi/mi* CMCs to which cDNA encoding each type of MITF had

been introduced using the retroviral vector. Overexpression of +-MITF but not of *mi*-MITF normalized the expression of p75 and the above-mentioned poor responses of *mi/mi* CMCs to NGF, indicating the involvement of +-MITF in p75 gene transactivation. Then, we analyzed the promoter of the p75 gene. Two CANNTG motifs recognized by bHLH-Zip-type transcription factors were conserved between the mouse and rat p75 promoters. One of these two CANNTG motifs was specifically bound by +-MITF. When the luciferase gene under the control of the p75 promoter was cotransfected into NIH/3T3 fibroblasts with cDNA encoding +-MITF or *mi*-MITF, luciferase activity increased significantly only when +-MITF cDNA was cotransfected. The mutation of this CANNTG motif abolished the transactivation effect of +-MITF, indicating that +-MITF transactivated the p75 gene, at least in part, through direct binding.

THE *mi* LOCUS on chromosome 6 of mice encodes a member of the basic-helix-loop-helix-leucine zipper (bHLH-Zip) protein family of transcription factors (hereafter called MITF).<sup>1,2</sup> The MITF of *mi/mi* mutant mice deletes one of four consecutive arginines in the basic domain.<sup>1,3,4</sup> The *mi/mi* mice show microphthalmia, depletion of pigment in hair and eyes, osteopetrosis, and a decrease in the number of mast cells.<sup>5-9</sup> In addition to the decrease in number, the phenotype of mast cells was abnormal in *mi/mi* mice.<sup>10-13</sup> In the skin of normal (+/+) mice, most mast cells were stained with berberine sulfate that bound heparin proteoglycan,<sup>14-17</sup> and half of them expressed the mouse mast cell protease-6 (MMCP-6) gene.<sup>11</sup> In contrast, only few mast cells were berberine sulfate–positive and MMCP-6 mRNA–positive in the skin of *mi/mi* mice.<sup>11</sup> Expression of the MMCP-6 gene was also markedly reduced in cultured mast cells (CMCs) derived from the spleen of *mi/mi* mice.<sup>10,13</sup>

Interleukin-3 (IL-3) or stem cell factor (SCF) promote proliferation and differentiation of mast cells.<sup>18,19</sup> In addition, nerve growth factor (NGF) has been reported to promote proliferation and differentiation of mast cells in the presence of suboptimal doses of IL-3.<sup>20</sup> The proliferative response of *mi/mi* CMCs to IL-3 was comparable to that of normal (+/+) CMCs. In contrast, *mi/mi* CMCs did not respond normally to both SCF and NGF.<sup>10,13</sup> The poor response of *mi/mi* CMCs to SCF was attributed to the reduced expression of *c-kit*, the receptor of SCF.<sup>10</sup> We previously reported that the poor response of *mi/mi* CMCs to NGF was attributable to impaired expression of the p75 NGF receptor.<sup>13</sup>

Transcription factors of the bHLH-Zip protein family, including MITF, recognize a consensus sequence of the CANNTG motif.<sup>21</sup> We have shown the binding of normal MITF (hereafter called +-MITF) to CANNTG motifs in the 5' flanking region of *c-kit*<sup>22</sup> and MMCP-6 genes,<sup>23</sup> the expression of which was markedly reduced in both *mi/mi* CMCs and *mi/mi* skin mast cells.<sup>10,11</sup> We have also shown the loss of DNA binding ability and nuclear localization potential of

the mutant MITF encoded by the *mi* mutant allele (hereafter called *mi*-MITF).<sup>24,25</sup> In the present study, we examined whether MITF directly regulated transcription of the p75 gene in mast cells. We introduced cDNA encoding +-MITF or *mi*-MITF into *mi/mi* CMCs and found that overexpression of +-MITF but not *mi*-MITF normalized the mRNA expression of the p75 gene and the poor response of *mi/mi* CMCs to NGF. +-MITF but not *mi*-MITF bound the CACTG motif in the 5' flanking region of the p75 gene. The luciferase gene under the control of the p75 promoter was transactivated by cotransfection of cDNA encoding +-MITF.

## MATERIALS AND METHODS

**Mice.** The original stock of C57BL/6-*mi*/+ (*mi*/+) mice was purchased from the Jackson Laboratory (Bar Harbor ME) and maintained in our laboratory by consecutive backcrosses to our own inbred C57BL/6 colony (>15 generations at the time of the present experiment). Female and male *mi*/+ mice were crossed together, and the resulting *mi/mi* mice were selected by their white coat color.<sup>5,6</sup>

**Reagents.** NGF purified from murine submaxillary glands was a gift from Drs A.M. Stanisz and J. Bienenstock (McMaster University, Hamilton, Ontario, Canada). On polyacrylamide gel electrophoresis, the preparation used in the present experiment showed a single protein band at 27 kD (2.5S NGF dimer).<sup>26</sup> Mouse recombinant murine (rm)IL-3 was a generous gift from Kirin Brewery Co (Tokyo, Japan).

**Cells.** Pokeweed mitogen-stimulated spleen cell-conditioned medium (PWM-SCM) was prepared according to the method described by Nakahata et al.<sup>27</sup> Mice of the *mi/mi* genotype and control C57BL/6-+/+ (+/+) mice were used at 2 to 3 weeks of age to obtain CMCs. Mice were killed by decapitation after ether anesthesia, and the spleens were removed. Spleen cells derived from *mi/mi* or +/+ mice were cultured in  $\alpha$ -minimal essential medium ( $\alpha$ -MEM) ICN Biomedicals, Costa Mesa, CA) supplemented with 10% PWM-SCM and 10% fetal calf serum (FCS; Nippon Biosupp Center, Tokyo, Japan). Half of the medium was replaced every 7 days, and greater than 95% of cells were CMCs 4 weeks after initiation of the culture.<sup>16</sup> The helper virus-free packaging cell line ( $\Psi$ 2)<sup>28</sup> was maintained in Dulbecco's modified Eagle's medium (DMEM) ICN Biomedicals) supplemented with 10% FCS. The NIH/3T3 fibroblast cell line was generously provided by Dr S.A. Aaronson (National Cancer Institute, Bethesda, MD) and maintained in DMEM supplemented with 10% FCS. The PC12 pheochromocytoma cell line was maintained in DMEM supplemented with 10% horse serum and 5% FCS. The IC-2 cell line was provided by Dr I. Yahara (Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan)<sup>29</sup> and maintained in  $\alpha$ -MEM supplemented with 10% PWM-SCM and 10% FCS.

**Construction of retrovirus vector and its infection.** Bluescript KS (-) plasmids (pBS; Stratagene, La Jolla, CA) containing the whole coding region of +-MITF or *mi*-MITF (pBS-+-MITF and pBS-*mi*-MITF, respectively) had been constructed in our laboratory.<sup>24,25</sup> A retroviral vector, pM5Gneo,<sup>30</sup> a derivative of myeloproliferative sarcoma virus vector, was a kind gift from Dr W. Ostertag (Universität Hamburg, Hamburg, Germany). The purified *Sma* I-*Hinc*II fragment from pBS-+-MITF or pBS-*mi*-MITF was introduced into the blunted *Eco*RI site of pM5Gneo. The resulting pM5Gneo-+-MITF and pM5Gneo-*mi*-MITF were transfected into

**Fig 1.** Normalization of p75 expression in *mi/mi* CMCs by introduction of +-MITF cDNA. The Northern blot was hybridized with a <sup>32</sup>P-labeled cDNA probe of p75 or  $\beta$ -actin.

**Table 1.** Normalization of Deficient <sup>125</sup>I-NGF Binding of *mi/mi* CMCs by Introduction of cDNA Encoding +-MITF

Cell Type	<sup>125</sup> I-NGF Binding (cpm/10 <sup>6</sup> cells)*		
	Total	Nonspecific	Specific

the packaging cell line ( $\Psi$ 2)<sup>28</sup> by the calcium phosphate precipitation method,<sup>31</sup> and neomycin-resistant  $\Psi$ 2 cell clones were selected by culturing in DMEM supplemented with 10% FCS and G418 (0.8 mg/mL; GIBCO-BRL, Grand Island, NY). For gene transfer, spleen cells obtained from *mi/mi* mice were incubated on an irradiated (30 Gy) subconfluent monolayer of virus-producing  $\Psi$ 2 cells for 72 hours in  $\alpha$ -MEM supplemented with 10% PWM-SCM and 10% FCS. Neomycin-resistant CMCs were obtained by continuing the culture in  $\alpha$ -MEM containing 10% PWM-SCM, 10% FCS, and G418 (0.8 mg/mL) for 4 weeks. In our previous study, Northern blot analysis showed apparent expression of the introduced +-MITF or *mi*-MITF cDNA in *mi/mi* CMCs, whereas mRNA expression of the endogenous *mi* gene was hardly detectable in either +/+ CMCs or *mi/mi* CMCs.<sup>22,23</sup>

**Northern blot analysis.** Total RNA from CMCs was prepared by the lithium chloride-urea method.<sup>32</sup> Northern blot analysis was performed using p75 and mouse  $\beta$ -actin<sup>33</sup> cDNAs labeled with  $\alpha$ -[<sup>32</sup>P]-deoxycytidine triphosphate ([dCTP] DuPont/NEN Research Products, Boston, MA; 10 mCi/mL) by random oligonucleotide priming as probes. For generation of the p75 probe, a *Pst*I/*Ava*I-digested 459-base pair fragment of p75 cDNA (nucleotide [nt] 390 to 848) was used.<sup>34</sup> After hybridization at 42°C, blots were washed to a final stringency of 0.2× SSC (1× SSC is 150 mmol/L NaCl and 15 mmol/L trisodium citrate, pH 7.4) at 50°C and subjected to autoradiography.

**Binding of <sup>125</sup>I-NGF to CMCs.** Aliquots of 50  $\mu$ L from CMC suspensions ( $2.0 \times 10^7$ /mL) were incubated for 45 minutes at 37°C with 50  $\mu$ L of various concentrations of <sup>125</sup>I-NGF (Amersham, Arlington Heights, IL) in  $\alpha$ -MEM containing 10% FCS. Radioactivity associated with CMCs was measured with a gamma counter ( $\gamma$  5000; Packard, Meriden, CT). Nonspecific binding was determined in parallel experiments in the presence of a 100-fold excess of unlabeled NGF. Specific binding was determined by subtracting the nonspecific binding from total counts.

**Clonal cell culture.** Methylcellulose culture was performed using a modification of the technique described by Nakahata et al.<sup>27</sup> Ten thousand CMCs were cultured in 1 mL  $\alpha$ -MEM containing 0.9% methylcellulose (Sigma, St Louis, MO), 30% FCS,  $10^{-4}$  mol/L 2-ME, 1% bovine serum albumin (Sigma), 50 U/mL penicillin, 50 mg/mL streptomycin, and 50 U/mL rmlL-3, with or without various doses of NGF. Culture dishes were incubated at 37°C in a humidified atmosphere of 5% CO<sub>2</sub> in air. Mast cell colonies containing at least 20 cells were identified according to the criteria

described by Nakahata et al<sup>27</sup> and counted under an inverted microscope.

**Staining.** Individual colonies were removed from methylcellulose cultures by Pasteur pipette under inverted-microscope visualization and placed onto glass slides. The preparations were fixed in Carnoy's fluid and stained with 0.025% berberine sulfate (Sigma) at pH 2.5. Fluorescent intensity of the cells in mast cell colonies was determined using a system photometer (OSP-1; Olympus Japan, Tokyo, Japan), which can detect the fluorescence of individual cells stained with berberine sulfate.<sup>14,20</sup> Because the fluorescence of ber-

berine sulfate was abolished by treatment with heparinase but not by treatment with chondroitinase ABC,<sup>14,16</sup> fluorescence was considered to indicate the presence of heparin proteoglycan.

**Electrophoretic gel mobility shift assay.** The production and purification of glutathione-S-transferase (GST)-+-MITF and GST-*mi*-MITF fusion proteins were described previously.<sup>24,25</sup> Oligonucleotides were labeled with  $\alpha$ -[<sup>32</sup>P]-dCTP by filling 5'-overhangs, and were used as probes for electrophoretic gel mobility shift assay (EGMSA). DNA binding assays were performed in a 20- $\mu$ L reaction mixture containing 10 mmol/L Tris hydrochloride (pH 8.0), 1 mmol/L EDTA, 75 mmol/L KCl, 1 mmol/L dithiothreitol, 4% Ficoll type 400, 50 ng poly(dI-dC), 25 ng of the labeled DNA probe, and 3.5 mg GST-+-MITF or GST-*mi*-MITF fusion protein. After incubation at room temperature for 15 minutes, the reaction mixture was subjected to electrophoresis at 14 V/cm at 4°C on a 5% polyacrylamide gel in 0.25× TBE buffer (1× TBE is 90 mmol/L Tris hydrochloride, 64.6 mmol/L boric acid, and 2.5 mmol/L EDTA, pH 8.3). The polyacrylamide gels were dried on Whatman 3MM chromatography paper (Whatman, Maidstone, UK) and subjected to autoradiography. Competitive DNA binding assays were performed as already described, except that the unlabeled competitive DNA was added to the reaction mixture before addition of GST-+-MITF fusion protein.

**Construction of effector and reporter plasmids.** pEF-BOS expression vector<sup>35</sup> was kindly provided by Dr S. Nagata (Osaka University Medical School, Osaka, Japan). The *Sma* I-*Hinc*II fragment of pBS-+-MITF or pBS-*mi*-MITF was introduced into the blunted *Xba* I site of pEF-BOS. The resulting pEF-+-MITF and pEF-*mi*-MITF expression vectors were used as effectors. The luciferase gene subcloned into pSP72 (pSPLuc)<sup>36</sup> was generously provided by Dr K. Nakajima (Osaka University Medical School, Osaka, Japan). To construct reporter plasmids, a DNA fragment containing a promoter region and the first exon (noncoding region) of the p75 gene (nt -250 to +35; +1 is the transcription initiation site)<sup>37</sup> was cloned into the upstream region of the luciferase gene in pSPLuc. The mutations were introduced by PCR with mismatched primers. Mutated products were verified by sequencing.

**Transient assay.** NIH/3T3 cells ( $5 \times 10^5$ ) were plated in a 10-cm dish 1 day before the procedure. Cotransfection with 10  $\mu$ g of a reporter, 100 ng of an effector, and 2  $\mu$ g of an expression vector containing the  $\beta$ -galactosidase gene was performed by the calcium phosphate precipitation method.<sup>31</sup> The expression vector containing the  $\beta$ -galactosidase gene was used as an internal control. For transfection of the genes into PC12 cells, the reporter, effector, and expression vector containing the  $\beta$ -galactosidase gene were added to the cell suspension ( $1 \times 10^7$ ) in 0.7 mL phosphate-buffered saline, mixed gently, and incubated on ice for 10 minutes. Since IC-2 cells expressed effector gene by themselves, the reporter and the expression vector containing the  $\beta$ -galactosidase gene were added to the

**Fig 3.** Binding of  $+$ -MITF to the CACTTG motif in the 5' flanking region of the p75 gene. (A) EMSA using GST- $+$ -MITF and GST- $mi$ -MITF fusion proteins. The 5'-ACGCCTCACTTGACTGCTCTGGACT oligonucleotide containing a CACTTG motif (probe 1, nt -149 to -125; numbers refer to the sequence shown in Fig 2) and the 5'-TGCCTTCA<sup>-31</sup>CCAGCTGCTCCCG oligonucleotide containing a CAGCTG motif (probe 2, nt -31 to -10) were used (CANNTG motifs are boxed). The DNA-protein complex is indicated by an arrowhead. (B) Competitive DNA binding assay with GST- $+$ -MITF. Two competitors were synthesized. Oligo 1 was identical to probe 1; oligo 3 had the mutation at the CACTTG motif (to CTCTAG). DNA-protein complexes are indicated by an arrowhead.

otide (probe 1; the hexameric motif is shown by the underscore) and the 5'-TGCCTTCA<sup>-31</sup>CCAGCTGCTCCCG-3' oligonucleotide (probe 2) were synthesized and labeled. EMSA was performed using GST- $+$ -MITF or GST- $mi$ -MITF fusion protein. No band was detected in the sample that contained no proteins (data not shown). A retarded band was observed in the sample containing probe 1 and GST- $+$ -MITF, but not in the sample containing probe 1 and GST- $mi$ -MITF (Fig 3A). In contrast to probe 1, probe 2 was not bound by either GST- $+$ -MITF or GST- $mi$ -MITF (Fig 3A).

To examine the specificity of binding of GST- $+$ -MITF to probe 1, we added unlabeled oligonucleotide that had the identical sequence with probe 1 (oligo 1, Fig 3B) to the reaction mixture containing GST- $+$ -MITF and probe 1. Binding of GST- $+$ -MITF to probe 1 was completely inhibited (Fig 3B). We then performed competition binding with oligonucleotide 3, in which the hexameric motif of probe 1 was mutated from CACTTG to CTCTAG (oligo 3, Fig 3B). Addition of the unlabeled oligo 3 did not affect binding of GST- $+$ -MITF to probe 1 (Fig 3B).

Then, we examined whether the CACTTG motif practically mediated the transactivation of  $+$ -MITF. The promoter region and the first exon of the p75 gene (nt -250 to +35) was cloned to the upstream of the luciferase gene. The expression plasmid containing  $+$ -MITF or  $mi$ -MITF cDNA was cotransfected into NIH/3T3 fibroblasts with the luciferase construct under the control of the p75 promoter. Coexpression of  $+$ -MITF but not  $mi$ -MITF significantly increased luciferase activity (Fig 4). Mutation of the CACTTG motif to CTCTAG abolished the transactivation ability of  $+$ -MITF.

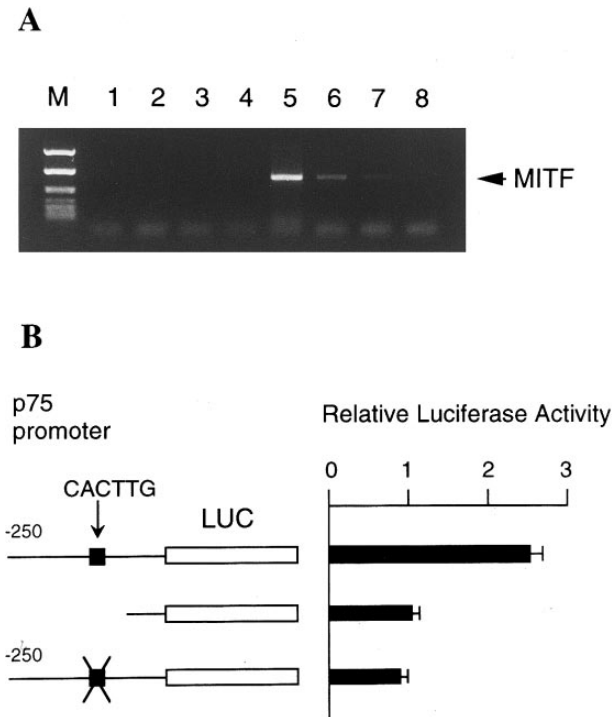

The effect of  $+$ -MITF on transcription activity of the p75 reporter construct appeared modest. Since NIH/3T3 cells did not express MITF (Fig 5A), we examined whether endogenous MITF can drive expression of the p75 reporter construct by using the IC-2 mast cell line that expressed MITF (Fig 5A). We introduced the luciferase gene under the control of the p75 promoter into IC-2 cells with electroporation. Luciferase activity was enhanced by the p75 promoter with the CACTTG motif, but transcription activity was abolished when the CACTTG motif was deleted or mutated (Fig 5B). When we compared reporter gene activity between IC-2 and NIH/3T3 cells, no significant difference was detectable, despite the expression of MITF in IC-2 cells. We next used PC12 cells that expressed p75 at high levels but did not express MITF. We cotransfected the luciferase gene under the control of the p75 gene and cDNA encoding  $+$ -MITF or  $mi$ -MITF. Cotransfection of even  $+$ -MITF did not increase luciferase activity (data not shown).

## DISCUSSION

NGF has been reported to influence the proliferation and phenotype of CMCs.<sup>20</sup> In our previous study, addition of

**Fig 4.** Effect of coexpression of cDNA encoding  $+$ -MITF or  $mi$ -MITF on luciferase activity. The luciferase gene under control of the normal or mutated p75 promoter was cotransfected to NIH/3T3 fibroblasts. All p75 promoters started from nt -250. Bars indicate the standard error of three assays.

**Fig 5. MITF expression and luciferase activity in IC-2 cells.** (A) RT-PCR analysis of expression of MITF mRNA. PCR products from RNAs of NIH/3T3 cells (lanes 1 to 4) and from RNAs of IC-2 cells (lanes 5 to 8) were electrophoresed in 1.0% agarose gel containing ethidium bromide with *Hae*III-digested Bluescript KS (-) plasmid DNA as a size marker (M). The amounts of RNA used for reverse transcription was 5.0  $\mu$ g (lanes 1 and 5), 0.5  $\mu$ g (lanes 2 and 6), 0.05  $\mu$ g (lanes 3 and 7), and 0.005  $\mu$ g (lanes 4 and 8), respectively. (B) Luciferase reporter gene promoter assay in IC-2 cells. The luciferase gene under control of the normal, deleted, or mutated p75 promoter was introduced into the IC-2 mast cell line with electroporation. All p75 promoters started from nt -250. Bars indicate the standard error of three assays.

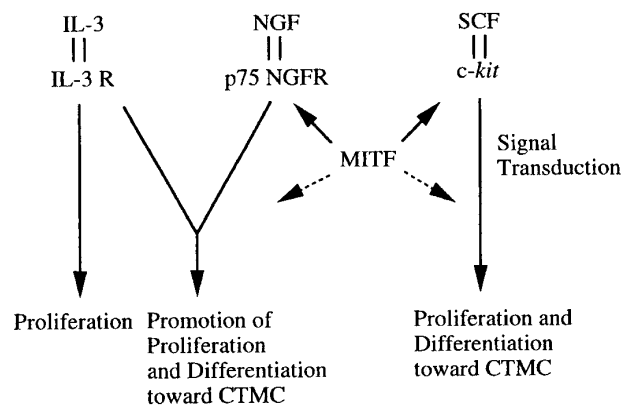

NGF to the suboptimal dose of rmIL-3 increased the number of colonies produced by *+/+* CMCs, but did not increase the number of colonies produced by *mi/mi* CMCs.<sup>13</sup> NGF also induced the connective tissue-type mast cell (CTMC)-like phenotype in *+/+* CMCs, but did not induce such a phenotype in *mi/mi* CMCs.<sup>13</sup> When NGF was added to rmIL-3, only *+/+* CMCs became berberine sulfate-positive, suggesting an increase in heparin content.<sup>14</sup> Expression of p75 was significantly lower in *mi/mi* CMCs than in *+/+* CMCs. Therefore, the poor proliferation and differentiation responses of *mi/mi* CMCs to NGF were attributed to deficient expression of p75.<sup>13</sup> In the present study, we introduced cDNA encoding *+-MITF* or *mi-MITF* into *mi/mi* CMCs with the retroviral vector, and found that overexpression of *+-MITF* but not *mi-MITF* normalized the poor expression of p75 message and the deficient binding of <sup>125</sup>I-NGF. The poor response of *mi/mi* CMCs to NGF was also normalized; this clearly indicated that it was due to the defective function of *mi-MITF*.<sup>24,25</sup>

We compared the nt sequence of the 5' flanking region of the mouse p75 gene with that of the rat p75 gene, and

two common CANNTG motifs were found. In these two CANNTG motifs, only CACTTG (nt -143 to -138) was specifically bound by *+-MITF*. The luciferase gene under the control of the p75 promoter was cotransfected into NIH/3T3 fibroblasts with cDNA encoding *+-MITF* or *mi-MITF*. Luciferase activity significantly increased only when cDNA encoding *+-MITF* was cotransfected. Moreover, mutation of the CACTTG motif to CTCTAG abolished the transactivation effect of *+-MITF*. Therefore, *+-MITF* appeared to transactivate the p75 gene by direct binding to the CACTTG motif.

We examined whether endogenous MITF in IC-2 cells can drive expression of the p75 reporter construct. Reporter gene activity of p75 in IC-2 cells was comparable to that of NIH/3T3 cells. *+-MITF* can enhance p75 expression by two mechanisms: a relatively weak effect on the promoter and other more indirect effects. As indirect effects, at least two mechanisms were hypothesized. As the first mechanism, *+-MITF* may activate expression of other transcription factors that upregulate expression of the p75 gene. As the second mechanism, *+-MITF* may induce nuclear translocation of other transcription factors that might enhance expression of the p75 gene. In fact, we reported that *mi-MITF* inhibited translocation of other proteins to the nucleus.<sup>25</sup>

There is another possible explanation for the relatively weak transcription potential of *+-MITF* on p75 expression despite significant biologic changes of mast cells in mice of the *mi/mi* genotype. In addition to the reduced expression of p75, some proteins used for signal transduction of p75 NGF receptor might also be regulated by *+-MITF*. We reported involvement of *+-MITF* in the expression of *c-kit*.<sup>22</sup> The transcriptional activity of *+-MITF* on *c-kit* gene expression was modest and comparable to that of the p75 gene. Dubreuil et al<sup>29</sup> suggested that the proteins encoded by the *mi* locus may be necessary for signal transduction by way of *c-kit*. The *+-MITF* may be involved in the transcription of protein(s) that may be used in the signal transduction of *c-kit* and p75 NGF receptor. A particular protein may be involved

**Fig 6. Scheme that may explain the effect of MITF on CMCs.** MITF may be involved in transcription of both the p75 NGF receptor and *c-kit*. Involvement of MITF in transcription of proteins that might be used for signal transduction via the p75 NGF receptor and *c-kit* may be speculated. IL-3R, IL-3 receptor; NGFR, NGF receptor.

in the two signal transduction pathways, or +MITF may regulate the expression of proteins that might be involved in each of them.

Taken together, IL-3, NGF, and SCF affect the proliferation and differentiation of CMCs. In combination with IL-3, NGF induced both proliferation of CMCs and differentiation toward the CTMC-like phenotype. On this point, the effect of IL-3 + NGF was comparable to that of SCF (Fig 6). At least part of the abnormality observed in *mi/mi* CMCs may be attributable to the low expression of p75 NGF receptor and *c-kit*. Although +MITF appeared to be involved in transcription of both the p75 NGF receptor and *c-kit*, the transcription potential of +MITF appeared modest. Therefore, +MITF might also be involved in transcription of proteins that may be used for signal transduction via the p75 NGF receptor and/or *c-kit* (Fig 6).
